

Body mass, cloacal temperature, morphometrics, breeding and molt of birds of the Serra das Araras region, Mato Grosso, Brazil

Yoshika Oniki and Edwin O. Willis

Departamento de Zoologia - UNESP - C. P. 199 - 13506-900 - Rio Claro, São Paulo, Brasil.

Recebido em 16 de agosto de 1996; aceito em 15 de setembro de 1998.

RESUMO. Peso, temperatura cloacal, morfometria, reprodução e muda de aves da região da Serra das Araras, Mato Grosso, Brasil. Neste trabalho, listamos os pesos, muda e temperaturas cloacais de aves de 86 espécies da Serra das Araras e vizinhanças, em Mato Grosso, Brasil. A reprodução ocorre na segunda metade do ano, seguido da muda.

PALAVRAS-CHAVE: Brasil, morfometria, peso, Serra das Araras.

KEY WORDS: Brazil, morphometrics, body mass, Serra das Araras.

Bird body masses are used in a wide range of disciplines such as avian physiology, morphology, theoretical modeling, ecology and community structure (Dunning 1993). However, only recently have body masses of Brazilian birds started to become available (Oniki 1978, 1980 a, b, 1986, Bierregaard 1988, Graves and Zusi 1990, Silva *et al.* 1990, Novaes and Lima 1991, Oniki and Willis 1991, 1993, Marini *et al.* 1997).

Here we report on body mass, cloacal temperatures and measurements for live birds of 86 species for several areas of Mato Grosso State, southwestern Brazil. We also report on brood patches, breeding, and molt.

Studies were conducted at the Ecological Station of Serra das Araras (15°38'S, 57°12'W) on 15 February - 15 March, 11-30 June, 22-29 July, 23 September - 5 October 1987, and 24-26 January 1988. Some data were obtained at Fundação Evangelista Buriti (15°25'S, 55°48'W) on 14-15 July 1987 and near the city of Pontes e Lacerda (15°20' S, 59°25' W) on 19 January 1988. Details of the vegetation of the areas and lists of birds are in Silva and Oniki (1988) and Willis and Oniki (1990).

Birds were captured in mist nets, weighed with Pesola scales to the nearest 0.2 g and cloacal temperatures measured with a quick measuring Schultheis thermometer. Other morphological measurements such as length of bill (chord from feather), tarsus, tail (between central feathers) and wing (unflattened chord) were obtained; sex and age of the bird were determined when possible. Molt of remiges, rectrices and contour feathers was checked. We also checked for vascularized, featherless or wrinkled (regressing) brood patches. Measurements were taken according to methods described in Oniki and Willis (1991). Most birds were released after measurement, but some are in the collection of the Departamento de Biologia, Universidade Federal do Mato Grosso, Cuiabá, MT. Classification follows Meyer de Schauensee (1970) in most cases.

Table 1 shows body mass and measurements. Body masses for *Uropelia campestris*, *Formicivora rufa* and *Hemitriccus striaticollis* are new for the literature (Dunning 1993).

Table 2 shows tail, wing and body molt, plus presence or absence of brood patch. Columbidae had very worn tail and wing feathers, plus pinfeathers on the body in February-March, but two *Columbina talpacoti* had heavily worn tails in July while tail and wing feathers were new and body pinfeathers were still present in others. Trochilidae had tail and wing new in June-July but in September, one *Eupetomena macroura* had a very worn tail and one *Thalurania furcata* was in wing and body molt. In January-March, many species showed scaly or wrinkled brood patches, sometimes with feathers growing on the sides of the bare area, or were caring for young out of the nest.

We captured young of *Crypturellus parvirostris* (March), *Geotrygon montana* (March), *Todirostrum latirostre* (Feb.), *Campylorhynchus turdinus* (Feb.), and *Cissopis leveriana* (Jan.). *Icterus icterus* was feeding a large young in a nest late in February but it was out of the nest in March. We found one nest of *Leptotila verreauxi* with two eggs on 26 September; one *Pitangus sulphuratus* nest had at least one young on 11 January; one adult *Columbina passerina* was flushed from a nest with two white eggs on 21 June, and one nest of *Coragyps atratus* had a nearly grown black young on 4 October. A female *Claravis pretiosa* had a shelled egg in the oviduct on 24 February, and individuals of *Furnarius rufus*, *Euphonia violacea*, and *Cacicus cela* were building nests on 22 September.

It seems that birds are nesting June-October, some to January-March, while in February-March, young are out of the nest, some with parents. The adult tail, wing and contour feathers are worn or in molt mostly in February-March.

ACKNOWLEDGMENTS

We appreciate a fellowship from the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) through the Projeto Polonoeste for fieldwork in Mato Grosso. Writing this paper was completed while Oniki held a fellowship from CNPq as an Associate Researcher at the

*no molt or wear; b - light wear; c - heavy wear; d - molt; tail-wing-body in that order, preceded by number if more than one individual; "aaa" individuals omitted

Universidade Estadual Paulista (UNESP), Rio Claro, SP. Dalci Oliveira, Benedito S. Ataguile and Michelle M. Willis helped with fieldwork. We thank Heloiso Figueiredo for permission to work and use the lodging at the Ecological Station of Serra das Araras; to Melanchton Silva at Fundação Evangelista do Buriti for hospitality and the administrators at the headquarters of the Secretaria do Meio Ambiente (SEMA) at Pontes e Lacerda. J. B. Dunning Jr. helped with the manuscript as well as two anonymous reviewers. This is publication n° 6 of the Institute for Studies of Nature.
