ABSTRACT: The Rio São Francisco hydrographic basin (SFHB) is the third largest river basin in Brazil and the only totally inserted within the country. The Rio São Francisco crosses the state of Minas Gerais in the direction southwest/north/northeast along c. 1,260 km, or about 47% of its total length. From its headwaters in the Serra da Canastra National Park, the river and its tributaries cross three major phytogeographical domains in Minas Gerais: the *cerrado*, the Atlantic Forest and the *caatinga*. This paper presents the avifauna of the upper and middle portions of the Rio São Francisco in Minas Gerais. Our data is the result of several years of field work by the authors, as well as an extensive research of the available literature on the avifauna from the headwaters of the Rio São Francisco, in São Roque de Minas, until the boundaries with the states of Goiás, to the northwest, and Bahia, to the north. We recorded a total of 614 birds in the Minas Gerais portion of the SFHB, included in 73 families and 25 orders. This corresponds to approximately 79% of the birds recorded in Minas Gerais, and approximately 33% of the Brazilian avifauna. We also highlight that 12% of the recorded species are considered threatened or near threatened at the state, national or global levels. The data presented here demonstrates the high importance of the Minas Gerais portion of the SFHB for bird conservation in Brazil.

KEY-WORDS: Atlantic Forest; avifauna; *caatinga*; *cerrado*; Minas Gerais; Rio São Francisco.

INTRODUCTION

The Rio São Francisco hydrographic basin (hereafter SFHB) is the third largest river basin in Brazil and the only totally inserted within the country. The Rio São Francisco crosses the state of Minas Gerais in the direction southwest/north/northeast along c. 1,260 km, or about 47% of its total length. Of the 36 tributaries of significant size, the main perennial are in Minas Gerais, namely: Paracatu, Urucuia, Carinhanha, Pardo, Grande and das Velhas (CODEVASF 2009, MI 2009).

From its headwaters in the Serra da Canastra National Park, the river and its tributaries cross three major phytogeographical domains in Minas Gerais: the *cerrado*, the Atlantic Forest and the *caatinga*. The *cerrado* occupies the largest area of SFHB in Minas Gerais, with more than 14 million ha, followed by the Atlantic Forest in the southern/southeast portion with approximate 3 million ha, and finally by the *caatinga*, with about 590,000 ha (CODEVASF 2009).

The great diversity of environments of the SFHB aroused the interest of many naturalists, mostly Europeans, which traversed the region making important records about its flora and fauna, especially during the first half of the 19th century. Attention should be paid to the significant contribution of Peter Wilhelm Lund (1801-1880) and Johannes Theodor Reinhardt (1816-1882), responsible for hundreds of bird specimens collected in various localities of the Rio São Francisco basin in Minas Gerais and which are deposited in the Museum of Zoology of the University of Copenhagen (ZMUC), Denmark (Krabbe 2007).

The aim of this work is to present a historical synthesis of the avifauna of the upper and middle portions of the Rio São Francisco in Minas Gerais (according to CODEVASF 2009), from its headwaters, in the Serra da Canastra National Park, until the boundaries with the states of Goiás, to the northwest, and Bahia, to the north (Figure 1).

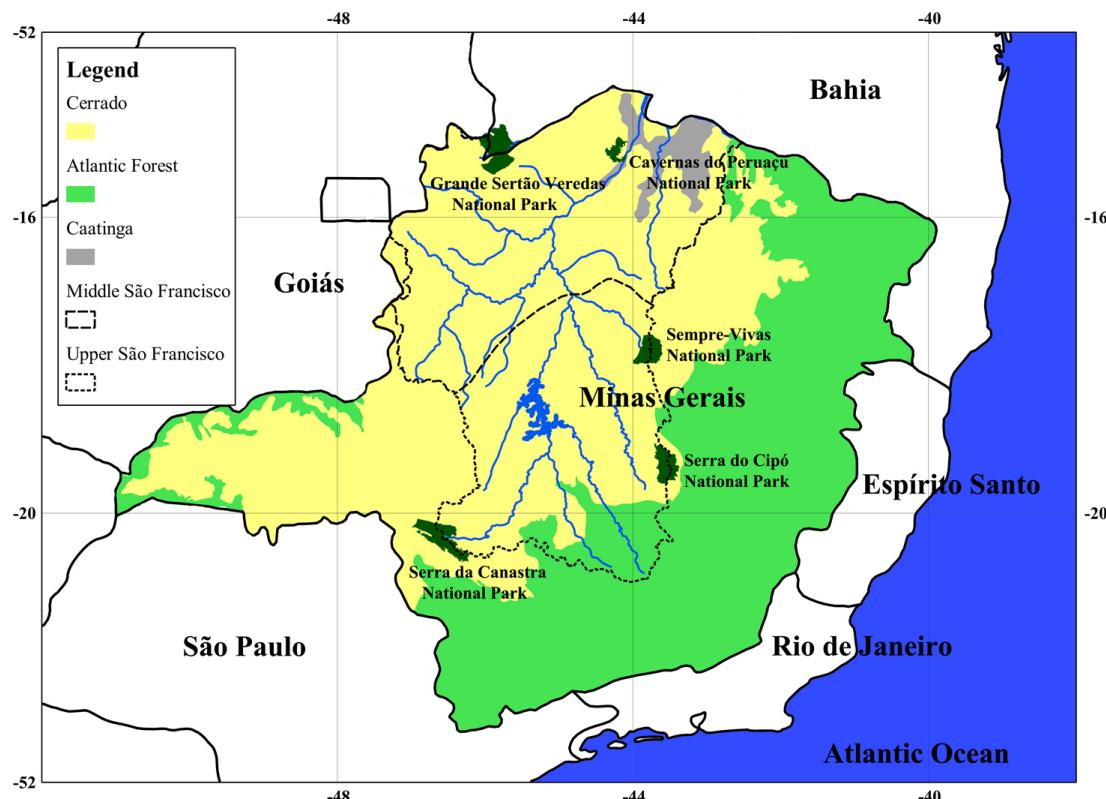

FIGURE 1. Limits of the Rio São Francisco hydrographic basin in Minas Gerais State, Brazil (dotted and dashed lines, with delimitations of the Upper and Middle parts of the basin). The river and its mains tributaries (in blue) and the main fully protected areas (in dark green) are shown.

METHODS

Study area

The channel of the Rio São Francisco is located among the crystalline terrains to the east (Espinhaço Range, in Minas Gerais) and the sedimentary plateaus of the “Espigão Mestre” to the west, which is a watershed between the basins of the Tocantins and São Francisco (CODEVASF 2009).

The climate of the São Francisco valley is characterized by regional rainfall. The highest values of annual precipitation are found in the upper São Francisco (ranging from 1,000 to 1,500 mm annually), especially between November and April (CODEVASF 2009). Along the transition from the upper to the middle São Francisco basin in Minas Gerais, these climatic conditions become more characteristic of a tropical semi-arid region, with the mean annual precipitation ranging from 600 to 1,400 mm, which occurs mainly between November and April (CODEVASF 2009). The average annual temperature is 23°C in the upper region, rising to 24°C toward the middle São Francisco (CODEVASF 2009). In some parts of the upper São Francisco, temperatures near 0°C can be recorded, even allowing the formation of frosts during the months from May to September. This occurs in the upper stretches of the Serra da Canastra National Park, which shelters the headwaters of the São Francisco (CODEVASF 2009).

Of the 503 municipalities of the SFHB, 240 of them (47.7%) are in Minas Gerais, and 203 (84.6%) are fully included within the hydrographic basin (CODEVASF 2009). Fifty-eight municipalities of Minas Gerais, i.e., 28.6% are fully inserted into the “Polígono das Secas”, a region which is subject to critical periods of prolonged drought (CODEVASF 2009).

Compilation of the avifauna from the SFHB in Minas Gerais

The data presented here is the result of several years of field work (between 1990 and 2012) by the authors in the Rio São Francisco basin in Minas Gerais. We also included in the compilation the species reported in the SFHB in Minas Gerais by Peter Wilhelm Lund and Johannes Theodor Reinhardt, recently reported by Krabbe (2007), and those listed in the summary of historical and systematic ornithology of Minas Gerais (Pinto 1952). We also searched for specimens collected in the SFHB in Minas Gerais, deposited in the following institutions: Departamento de Zoologia da Universidade Federal de Minas Gerais (DZUFMG), Departamento de Zoologia da Universidade Federal de Pernambuco (UFPE), Museu de Ciências Naturais da Pontifícia Universidade Católica de Minas Gerais (MCNA) and Museu de Zoologia da Universidade de São Paulo (MZUSP), the latter based on specimens collected by GAB on an expedition to the municipality

of Jaíba. Additionally, in order to complement the data obtained in the field and museums, we conducted an extensive research on the available literature about the avifauna of the SFHB in Minas Gerais (Willis & Oniki 1991, Whitney *et al.* 1995, Parrini & Pacheco 1997, Sick 1997, Silveira 1998, Anciães *et al.* 2001, Kirwan *et al.* 2001, Kirwan *et al.* 2004, Marini & Lopes 2005, Rodrigues *et al.* 2005, Zorzin *et al.* 2005, Vasconcelos *et al.* 2006, Vasconcelos & D'Angelo-Neto 2007, Dias & Rodrigues 2008, Firme *et al.* 2008, Lopes *et al.* 2008, Vasconcelos *et al.* 2008a, Vasconcelos & Diniz 2008, Faria *et al.* 2009, Moura & Correa 2010, Bessa *et al.* 2011, Lopes *et al.* 2010, Lopes *et al.* 2011, Mazzoni & Perillo 2011, Mazzoni *et al.* 2011, Vasconcelos *et al.* 2011, Mazzoni *et al.* 2012b). We attempted to include all the municipalities embraced by the SFHB in Minas Gerais, for which bird surveys were available. Care was taken for those species recorded in municipalities located in the Espinhaço Range, since this massif represents the watershed between the Rio São Francisco basin, to the west, and Rios Doce, Jequitinhonha and Pardo, to the east. Thus, we discarded those species recorded in this region, for which it was not possible to verify if the record was actually made on the western slope of the Espinhaço Range.

When applicable, the species were classified as endemics to the phytogeographical domains of the Atlantic Forest (Brooks *et al.* 1999, Ridgely *et al.* 2007), the *cerrado* (Silva 1995, Cavalcanti 1999, Silva & Bates 2002), the *caatinga* (Ridgely & Tudor 1989, 1994, Stotz *et al.* 1996, Sick 1997, Olmos *et al.* 2005, Vasconcelos & D'Angelo-Neto 2007, Santos 2008) and the eastern Brazilian mountaintops (Vasconcelos & Rodrigues 2010). The species were also classified concerning their conservation status according to the state (COPAM 2010), national (Silveira & Straube 2008) and global (IUCN 2010) lists of threatened species. The systematic order and scientific names follow the Brazilian Committee of Ornithological Records (CBRO 2011).

RESULTS AND DISCUSSION

Richness of the avifauna in the SFHB in Minas Gerais

Based on our field work, we recorded a total of 548 bird species in the SFHB in Minas Gerais. By assembling this data with the bibliography and museum specimens, a total of 614 bird species was recorded in the basin in Minas Gerais, belonging to 73 families and 25 orders (Appendix). This number corresponds to approximately 79% of the avifauna recorded for the entire state of Minas Gerais (Mattos *et al.* 1993, Vasconcelos *et al.* 2006) and c. 33% of the species known to occur in Brazil (CBRO 2011). Amongst the 614 species recorded, 74 (12%)

are framed into a category of threat at state, national or global levels (Silveira & Straube 2008, COPAM 2010, IUCN 2010).

Questionable records

Of the species mentioned in the bibliography, we list below those considered questionable, and that may be the result of mislabeling or misidentification problems, since their ranges are not known to reach the SFHB in Minas Gerais (these species were marked with * in the Appendix).

Some species are typical of the Atlantic Forest coastal mountains or of lowland rainforests, as is the case of the Black-capped Screech-Owl (*Megascops atricapilla*), mentioned by Krabbe (2007) based on Lund's records for the following localities: Lagoa Santa, Sete Lagoas, Sumidouro and Curvelo. However, according to this author, there are no specimens deposited in ZMUC, so that this record might have been based merely on Lund's observations, and without a precise identification. If there was collecting, the specimens may have been lost over time, making it impossible to confirm its presence in the study area. There is also the possibility that Lund or some ZMUC's curator made confusion when labeling these specimens, by swapping labels or even annotating as "Lagoa Santa" in the labels of specimens not labeled *in situ*. This may be the case, for example, of *Himantopus mexicanus*, which would have been collected in Lagoa Santa and Sumidouro. Krabbe (2007) points out that the identification of this species is not safe once, according to the author, the collected specimen was lost or the location of the collection is not properly indicated on the label. This situation allows us to consider that perhaps the collected individual belongs to the congeneric species *H. melanurus*, pretty common in the probable collecting site. Nevertheless, the presence of *H. mexicanus* within the limits of the SFHB in Minas Gerais was recently documented by birdwatchers in the municipality of Belo Horizonte (Pedersoli 2012).

Another point that should be noted is that many specimens were collected by Lund during his stay or visit to various points of the Atlantic Forest in the states of Rio de Janeiro, São Paulo and Minas Gerais (Krabbe 2007). Besides that, some species have records cited by Pinto (1952) in localities of the SFHB in Minas Gerais, supposedly collected by both Danish naturalists (Lund and Reinhardt), even though there are no voucher specimens from these regions currently deposited in ZMUC (Krabbe 2007). Therefore, we consider questionable the records of Brazilian Ruby (*Clytolaema rubricauda*), Short-tailed Antthrush (*Chamaezza campanisona*), Black-capped Becard (*Pachyramphus marginatus*), Brown Tanager (*Orchesticus abeillei*), Long-tailed Potoo (*Nyctibius aethereus*), Spot-billed Toucanet (*Selenidera maculirostris*),

Yellow-throated Woodpecker (*Piculus flavigula*) and Spot-backed Antshrike (*Hypoedaleus guttatus*). In the particular case of *H. guttatus*, Christiansen & Pittier (1997) report recent observations (from June to November 1987) of this species in the Lagoa Santa region. However, even after several years of efforts in the region's forests, we have never found this typical coastal Atlantic Forest species, and we suggest that the observations of these authors may have been based on a misidentification. The same goes for Wied's Tyrant-Manakin (*Neopelma aurifrons*), Eye-ringed Tody-Tyrant (*Hemitriccus orbitatus*) and Olivaceous Flatbill (*Rhynchocyclus olivaceus*). This becomes yet clearer when we verify the absence of these species even in areas of Atlantic Forest not far from Lagoa Santa, such as the eastern slope of Serra do Cipó (Rodrigues *et al.* 2011) and the Serra do Caraça (Vasconcelos & Melo-Júnior 2001), which harbours several species endemic to this phytogeographical domain.

In the case of the Purple-winged Ground-Dove (*Claravis geoffroyi*), an Atlantic Forest endemic associated with massive bamboo seeding events (Areta *et al.* 2009), the only available record for the SFHB in Minas Gerais is based on four specimens collected by Lund at Lagoa Santa (Krabbe 2007). Apart from this record, there are reports from old fowlers of northern Minas Gerais about its occurrence, over 60 years ago, in the municipality of Bocaiúva (SDN, based on interviews with locals). Despite the possibility that some bamboo species has seeded in these regions in the past, attracting individuals of the species, we believe some sort of confusion in the labeling has occurred, as mentioned above.

The Blue-bellied Parrot (*Trichoglossus malachitacea*) was mentioned for Lagoa Santa based on reports from Burmeister, cited by Pinto (1952). There is no mention of collecting specimens, so that this record should be based on a misidentification, since Lagoa Santa is very far from the species known range, besides the fact that the Blue-bellied Parrot has never been found by Lund and/or Reinhardt, who sampled the region quite well (Krabbe 2007).

With respect to dubious records made in *caatinga* or *cerrado* areas of the SFHB in Minas Gerais, the Brown-throated Parakeet (*Aratinga pertinax*), was mentioned by Willis & Oniki (1991) for the municipality of Januária. We believe it is the result of misidentification by the authors, especially due to the lack of proper documentation that supports the occurrence of the species in the region, whose known range is distant thousands of kilometers from the SFHB (Forshaw 2010).

In the case of the Forbes's Blackbird's (*Curaeus forbesi*), published records for the SFHB in northern Minas Gerais (Willis & Oniki 1991, Kirwan *et al.* 2004, Vasconcelos *et al.* 2006), are also probably the result of misidentification. Thus, we agree with Mazzoni *et al.* (2012) that a probable confusion of this species with

the Scarlet-throated Tanager (*Compsothraupis loricata*) might have occurred. The Scarlet-throated Tanager is an atypical Thraupidae much common in northern Minas Gerais and whose behaviour and vocalizations resemble those of some Blackbirds, besides the fact that individuals possessing the scarlet throat (species diagnosis) are very scarce in the SFHB in Minas Gerais.

***Caatinga* birds in the SFHB in Minas Gerais**

The *caatinga* shelters 22 endemic birds, of which 19 (86%) occur in the SFHB in Minas Gerais (Appendix). According to Machado *et al.* (2005), the White-browed Guan (*Penelope jacucaca*) and the Moustached Woodcreeper (*Xiphocolaptes falcirostris franciscanus*) are considered vulnerable, while the White-browed Antpitta (*Hylopezus ochroleucus*) and the São Francisco Sparrow (*Arremon franciscanus*) are near threatened. Among the *caatinga* and central Brazilian dry forests typical species, the Minas Gerais Tyrannulet (*Phylloscartes roquettei*) is critically endangered (Silveira & Straube 2008), the Wagler's Woodcreeper (*Lepidocolaptes wagleri*) is vulnerable (Silveira & Straube 2008) and the Caatinga Black-Tyrant (*Knipolegus franciscanus*) are near threatened (IUCN 2010).

***Cerrado* birds in the SFHB in Minas Gerais**

Twenty (61%) of the 33 endemic *cerrado* birds (Silva 1995, Cavalcanti 1999, Silva & Bates 2002) were recorded in the SFHB in Minas Gerais (Appendix). However, recent analysis (Vasconcelos *et al.* 2003, Lopes 2008, Vasconcelos 2008, Vasconcelos & Rodrigues 2010) showed that four of these species would be better characterized as endemic to the eastern Brazilian mountaintops rather than to the *cerrado* (see below).

One of the most threatened species of the SFHB in Minas Gerais is the Brazilian Merganser (*Mergus octosetaceus*), whose distribution in this region is restricted to the upper São Francisco, in the Serra da Canastra. Other threatened species found in this region are the Cock-tailed Tyrant (*Alectrurus tricolor*), the Sharp-tailed Tyrant (*Culicivora caudacuta*), the Ochre-breasted Pipit (*Anthus nattereri*), the Campo Miner (*Geositta poeciloptera*), the Dwarf Tinamou (*Taoniscus nanus*), the Lesser Nothura (*Nothura minor*) and the Brasilia Tapaculo (*Scytalopus novacapitalis*; Silveira 1998).

Birds from the *campos rupestres* in the SFHB in Minas Gerais

The *campos rupestres* have a characteristic flora and avifaunal elements strongly associated with this ecosystem. Four bird species found in the SFHB are endemic to the eastern Brazilian mountaintops (Vasconcelos 2008, Vasconcelos & Rodrigues 2010), being found mainly in this type of vegetation, namely: Hyacinth Visorbearer

(*Augastes scutatus*), Cipo Canastero (*Asthenes luizae*), Gray-backed Tachuri (*Polyictus superciliaris*) and Pale-throated Serra-Finch (*Embernagra longicauda*).

In stretches of transitional vegetation between *campos rupestres* and forest edges and second growths (*capoeiras*), especially near the border of the Atlantic Forest, species such as the Serra Antwren (*Formicivora serrana*), the Hangnest Tody-Tyrant (*Hemitriccus nidipendulus*), the Velvety Black-Tyrant (*Knipolegus nigerrimus*) and the Gilt-edged Tanager (*Tangara cyanovenstris*) are also found. Also, many typical and/or endemic hummingbirds of the Atlantic Forest are found exploiting flowering plants of the *campos rupestres*, as is the case of the Black Jacobin (*Florisuga fusca*), the White-throated Hummingbird (*Leucochloris albicollis*), the Violet-capped Woodnymph (*Thalurania glaucopis*) and the Scale-throated Hermit (*Phaethornis eurynome*).

Atlantic Forest birds in the SFHB in Minas Gerais

The Atlantic Forest section of the SFHB in Minas Gerais, although representing a lesser extent when compared to the *cerrado* coverage, presents a richer avifauna in terms of endemism. Of the 199 species considered endemic to the Atlantic Forest (Brooks *et al.* 1999), 78 (39%) were recorded in the Minas Gerais portion of the SFHB (Appendix).

It is noteworthy that many mountains act as watershed between the hydrographic basins of the São Francisco and Doce rivers, as in the case of the Serra da Gandarela and the Serra do Cipó, where the limits between the *cerrado* and Atlantic Forest meet (Rodrigues *et al.* 2005, Ribeiro *et al.* 2009). These mountainous areas represent the more inland occurrences of many endemisms of the Atlantic Forest, such as the Yellow-eared Woodpecker (*Veniliornis maculifrons*) and the Serra do Mar Tyrant-Manakin (*Neopelma chrysolophum*).

Among the threatened species, we highlight the Marsh Tapaculo (*Scytalopus iraiensis*), only recently recorded in the SFHB, occurring in the highest parts of the Serra do Cipó, Serra da Canastra (Vasconcelos *et al.* 2008b) and other mountains of the Quadrilátero Ferrífero region.

Bird conservation in the SFHB in Minas Gerais

The Minas Gerais portion of the SFHB has high importance for the conservation of the Brazilian avifauna, especially because of the huge variety of habitats found throughout its length. The main reason for this is the presence in the basin of three phytogeographic domains (*cerrado*, *caatinga* and Atlantic Forest) and its transitional zones. Also noteworthy is the wide altitudinal variation, of less than 500 m in the Rio São Francisco valley, to over 1,800 m in its southern portion, represented by the higher mountains of the Quadrilátero Ferrífero, such

as the Serras do Batatal and da Piedade. This enormous climatic-vegetational diversity fosters the existence of a high richness of birds, including various endemisms of the three phytogeographic domains mentioned above, besides those species restricted to the *campos rupestres*. Thus, the Minas Gerais portion of the SFHB is unique within the entire Rio São Francisco basin and representative areas of all this vegetational complex should be preserved to maintain and conserve its biodiversity.

The total area of the SFHB corresponds to approximately 64 million hectares. Of this total, circa 23.5 million, or 36% correspond to the Minas Gerais portion (CODEVASF 2010). Over the years, the federal and state governments have been investing in the creation of protected areas (PAs) focused, among other objectives, on the protection and conservation of biological diversity. Recent data (IEF 2010, ICMBio 2010) indicates that 59 protected areas are located within the limits of the SFHB in Minas Gerais, among those of full protection (Parks, Biological Reserves, Ecological Stations, among others) or sustainable use (National or State Forests, Environmental Protection Areas, Natural Monuments, etc.). These 59 PA's cover an approximate total of 2 million hectares, that is, the modest percentage of 8.5% of the entire area of the SFHB in the state of Minas Gerais. Even though the PA's are relatively well distributed among the phytogeographical domains present within the SFHB in the state, this percentage can be considered low, especially if one takes into account the importance that these environments pose to bird conservation in this region. Moreover, protecting areas of notorious importance for the conservation of wildlife, particularly the avifauna, under the tutelage of the law, are means to prevent the overwhelming advance of projects and activities that cause negative impacts on wildlife. Although these projects are important to meet the demands of the country in terms of wealth and jobs generation, they are known to have strong and irreversible negative impacts on biodiversity. In this sense, efforts directed not only to the creation but also to promote the land regularization and development of management plans for the existing protected areas are necessary. The mountaintops in the eastern SFHB, and the *veredas* and oxbow lakes, permanent or temporary, in the west, are known as places of genuine importance to the birds that use them, whether in the whole or part of their life cycles. Refined field studies on the diversity of birds, prioritizing areas as suggested by Drummond *et al.* (2005), should be seen as a priority by environmental agencies at both federal and state levels. These studies must be associated with policies that allow the identification, creation and effective implementation of protected areas, preferably those fully protected. Therefore, some regions should receive special attention from the governments to increase the knowledge of the local avifauna, and hence subsidize policies of creation and regulation of fully

protected areas in the Minas Gerais portion of the SFHB. Some examples are: the Serra da Gandarela, located in the southern Espinhaço Range and classified in the Atlas for Biodiversity Conservation in Minas Gerais (Drummond *et al.* 2005) as of “Extreme Biological Importance”; unique environments such as the mountaintops of the Central Espinhaço and the foothills of the Serra do Cabral, both categorized as of “Special Biological Significance”; the mosaics of oxbow lakes and veredas at the regions of João Pinheiro, Vazante and Brasilândia de Minas, along the upper/middle Rio Paracatu, also considered as “Extreme Biological Importance”.

ACKNOWLEDGEMENTS

MGD is grateful to IBAMA for making field surveys possible. LGM is grateful to CNPq (Process 134779/2011-8) for the masters scholarship granted. SDN is grateful to FAPEMIG for the PhD scholarship granted. MFV thanks to Drs. Marcos Rodrigues and José Maria Cardoso da Silva for facilitating access to the collections of DZUFMG and UFPE, respectively. GAB is grateful to Dr. Luís Fábio Silveira and CEMAVE for making possible her participation in an expedition to the Jaíba region.

Associate Editor: Marcos Pérsio Dantas Santos

APPENDIX:

Birds recorded in the Minas Gerais portion of the Rio São Francisco hydrographic basin.

Taxon: (MA) Atlantic Forest endemic species; (CE) *cerrado* endemic species; (CAA) *caatinga* endemic species; (TM) Eastern Brazilian mountaintops endemic species; (*) Records considered doubtful for the SFHB in Minas Gerais (see Results and Discussion).

Status: (Vu^a) Species categorized as “vulnerable” in the Brazilian national list of threatened species (Silveira and Straube 2008); (Cr^a) Species categorized as “critically endangered” in the Brazilian national list of threatened species (Silveira and Straube 2008); (Vu^b) Species categorized as “vulnerable” in the list of threatened species of the Minas Gerais State (COPAM 2010); (En^b) Species categorized as “endangered” in the list of threatened species of Minas Gerais State; (Cr^b) Species categorized as “critically endangered” in the list of threatened species of the Minas Gerais State (COPAM 2010); (Nt^c) Species categorized as “near threatened” in the global list (IUCN 2010); (Vu^c) Species categorized as “vulnerable” in the global list (IUCN 2010); (En^c) Species categorized as “endangered” in the global list (IUCN 2010); (Cr^c) Species categorized as “critically endangered” in the global list (IUCN 2010).

Authors: Data collected in the field by the authors between the years 1990 and 2012.

DZUFMG: Specimens deposited in the Departamento de Zoologia da Universidade Federal de Minas Gerais.

UFPE: Specimens deposited in the Departamento de Zoologia da Universidade Federal de Pernambuco.

MCNA: Specimens deposited in the Museu de Ciências Naturais da PUC Minas.

MZUSP: Specimens deposited in the Museu de Zoologia da Universidade de São Paulo, collected by GAB in the Jaíba/MG region.
